Motivation: confusing legends

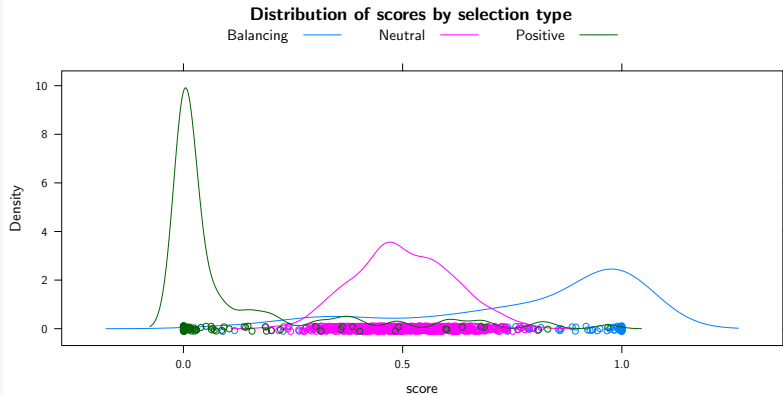

How to add direct labels to some common plots

Recent developments in direct labeling

Conclusions

# Problem 1: legend inconsistent with data

```
library(lattice)
dens <- densityplot(~score,locl,groups=type,
  auto.key=list(space="top",columns=3),n=500,
  main="Distribution of scores by selection type")
print(dens)
```

## Problem 2: too many classes render legend unreadable

```
data(BodyWeight, package="nlme")
library(ggplot2)
ratplot <- ggplot(BodyWeight, aes(Time, weight, colour=Rat)) +
  facet_grid(.~Diet) +
  geom_line()
print(ratplot)
```

Motivation: confusing legends

How to add direct labels to some common plots

Recent developments in direct labeling

Conclusions

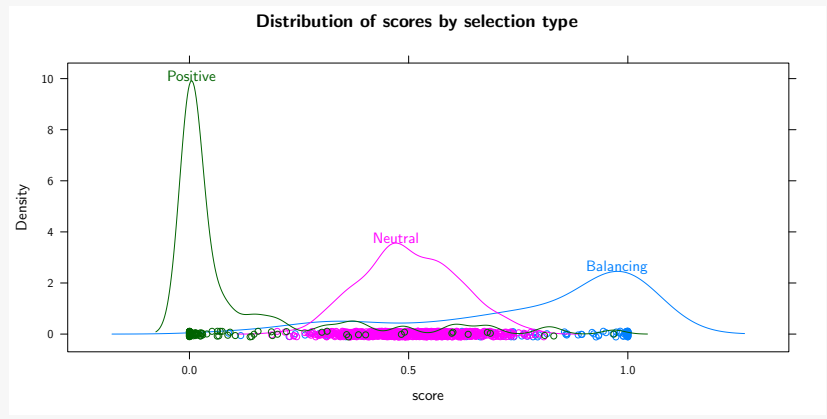

# The protocol I use for everyday plots in practice:

Do as many steps as needed until the plot is readable:

1. Make a lattice or ggplot2 plot `p` using colors and default legends.
2. Try the default direct labels: `direct.label(p)`.
3. Check to see if another Positioning Method exists on <http://directlabels.r-forge.r-project.org/docs/index.html> then use `direct.label(p, "method")`.
4. If no Positioning Methods exist you can always write your own.

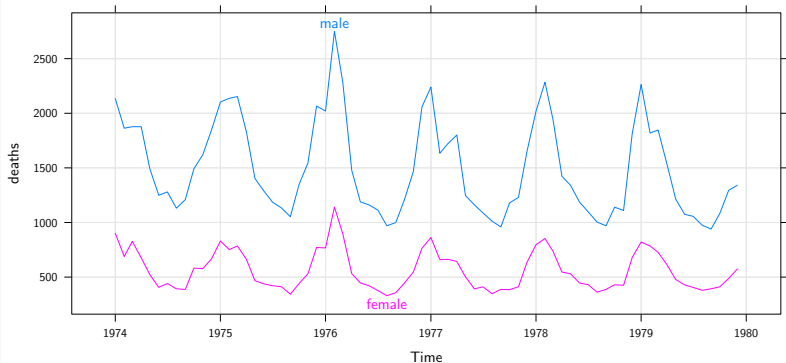

# Add default direct labels at the mode of each density

```
library(directlabels)  
direct.label(dens)
```

## With 2 groups, we label the min and max points

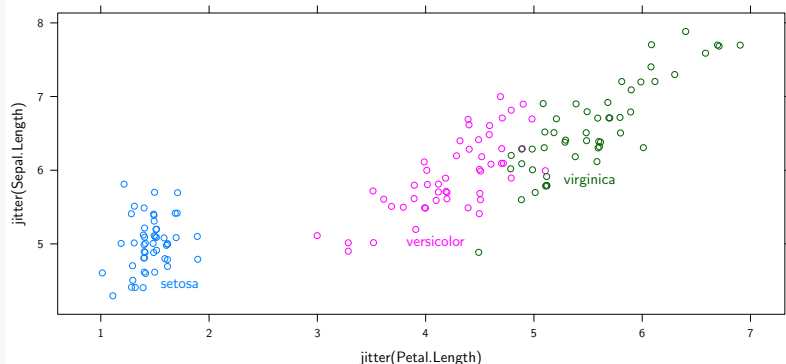

```
p <- xyplot(deaths~Time,uk.lung,  
            groups=sex,type=c("l","g"))  
direct.label(p)
```

## Label a scatterplot of the iris data by species

```
set.seed(1)
iris <- xyplot(jitter(Sepal.Length)~jitter(Petal.Length),
              iris, groups=Species)
direct.label(iris)
```

# Default direct labels for lineplots

```
direct.label(ratplot)
```

# Look up the Positioning Method on the directlabels website

```
direct.label(ratplot, "last.qp")
```

# Construct your own custom Positioning Method

```
rp2 <- ratplot+  
  xlim(0,70)+ylim(150,650)  
big.last <- list(cex=1.5,"last.qp")  
direct.label(rp2,"big.last")
```

## Direct label the LASSO path to visualize variables

```
lasso.plot <-  
ggplot(path, aes(arclength, standardized.coef, colour=variable)) +  
  geom_line(aes(group=variable)) +  
  opts(title="LASSO path for prostate cancer data  
calculated using the LARS") +  
  xlim(0, 20)  
direct.label(lasso.plot)
```

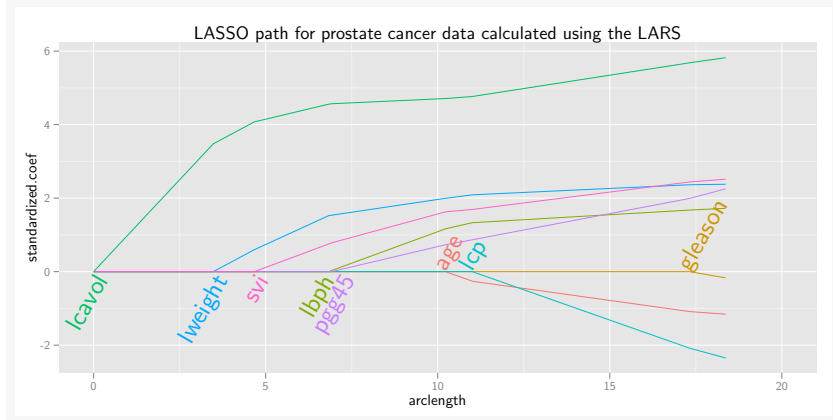

# Label the zero point to emphasize variable importance

```
direct.label(lasso.plot, "lasso.labels")
```

# Increase text size to make reading easier

```
direct.label(lasso.plot, list(cex=2, "lasso.labels"))
```

How to add direct labels to some common plots

Recent developments in direct labeling

Conclusions

## Changes in recent versions of directlabels

directlabels version plotting package	< 2.0 lattice	< 2.0 ggplot2	≥ 2.0 lattice	≥ 2.0 ggplot2
basic Positioning Methods	✓	✓	✓	✓
smart Positioning Methods that avoid label collisions	✓		✓	✓
redraw labels after window resize			✓	✓
fontface and fontfamily text parameters	✓		✓	✓
label black and white plots	✓		✓	✓
label aesthetics other than color				✓

# Label a scatterplot of the iris data by species

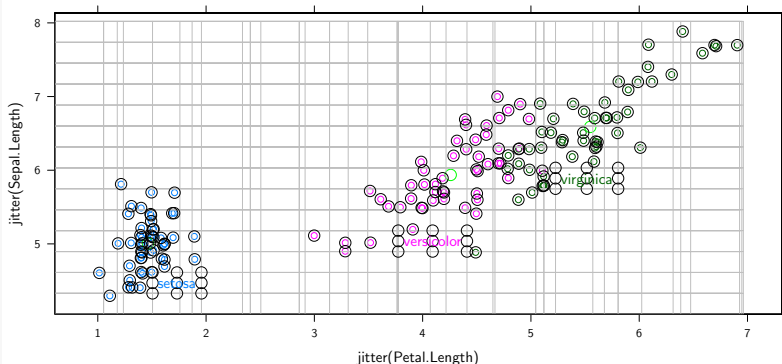

```
direct.label(iris)
```

## Show the grid for the search

Find a label position on a grid (grey rectangles)  
that is near the center of each point cloud (green dots),  
but does not overlap any points or other labels (black dots).

```
direct.label(iris, debug=TRUE)
```

# Increase text size **before** calculating label positions

```
rp2 <- ratplot+  
  xlim(0,70)+ylim(150,650)  
big.last <- list(cex=1.5,"last.qp")  
direct.label(rp2,"big.last")
```

# Show the label borders used in the position calculation

```
direct.label(rp2,  
  list("big.last",  
        "calc.bboxes",  
        "draw.rects"))
```

# Label positions for lineplots are the solutions of a QP

Assume that for each text label  $i = 1, \dots, k$  we have its position  $t_i$  and height  $h_i$ .

Then optimal direct labels do not overlap, and are as close as possible to the target locations:

$$\min_{b \in \mathbb{R}^k} \sum_{i=1}^k (b_i - t_i)^2 = \|b - t\|^2$$

$$\text{subject to } b_{i+1} \geq b_i + h_{i+1}/2 + h_i/2, \quad \forall i = 1, \dots, k-1$$

This is a quadratic program (QP). QPs are convex so there is a unique global minimum which corresponds to the best labels.

We can solve this using `quadprog::solve.QP()` and use the optimal  $b$  for the direct label positions.

## Start with boxes at the end of each line

```
direct.label(rp2,list("last.points",cex=1.5,  
"calc.bboxes",  
"draw.rects"))
```

## Adjust box height if desired

```
direct.label(rp2,list("last.points",cex=1.5,"calc.boxes",  
  dl.trans(h=h+h/3),"calc.borders",  
  "draw.rects"))
```

# Apply QP solver to get optimal labels

```
direct.label(rp2,list("last.points",cex=1.5,"calc.bboxes",  
  dl.trans(h=h+h/3),"calc.borders",  
  qp.labels("y","h")))
```

Motivation: confusing legends

How to add direct labels to some common plots

Recent developments in direct labeling

Conclusions

# What directlabels is NOT

- ▶ Automatic publication-quality direct labels.  
(some manual tweaking will always be necessary)
- ▶ Optimal labels for individual points on scatterplots.  
(it is a bit more complicated)

# Use directlabels instead of confusing legends!

- ▶ Works with lattice and ggplot2.
- ▶ Sensible defaults.
- ▶ Useful in everyday plots in practice.
- ▶ Smart Positioning Methods that avoid label collisions.
- ▶ Customizable: you can write your own Positioning Methods.

# Future work

- ▶ Automatically adjust xlim/ylim so labels stay on plot region?
- ▶ Contourplot labels as in `contour()`?
- ▶ Label using images instead of textual factor names?
